Experiment No: 04

Experiment Name: SDN Controllers and Mininet

Objectives:

- Install and use traffic generators as powerful tools for testing network performance.
- Install and configure SDN Controller
- Install and understand how the mininet simulator works
- Implement and run basic examples for understanding the role of the controller and how it interact with mininet

Theory:

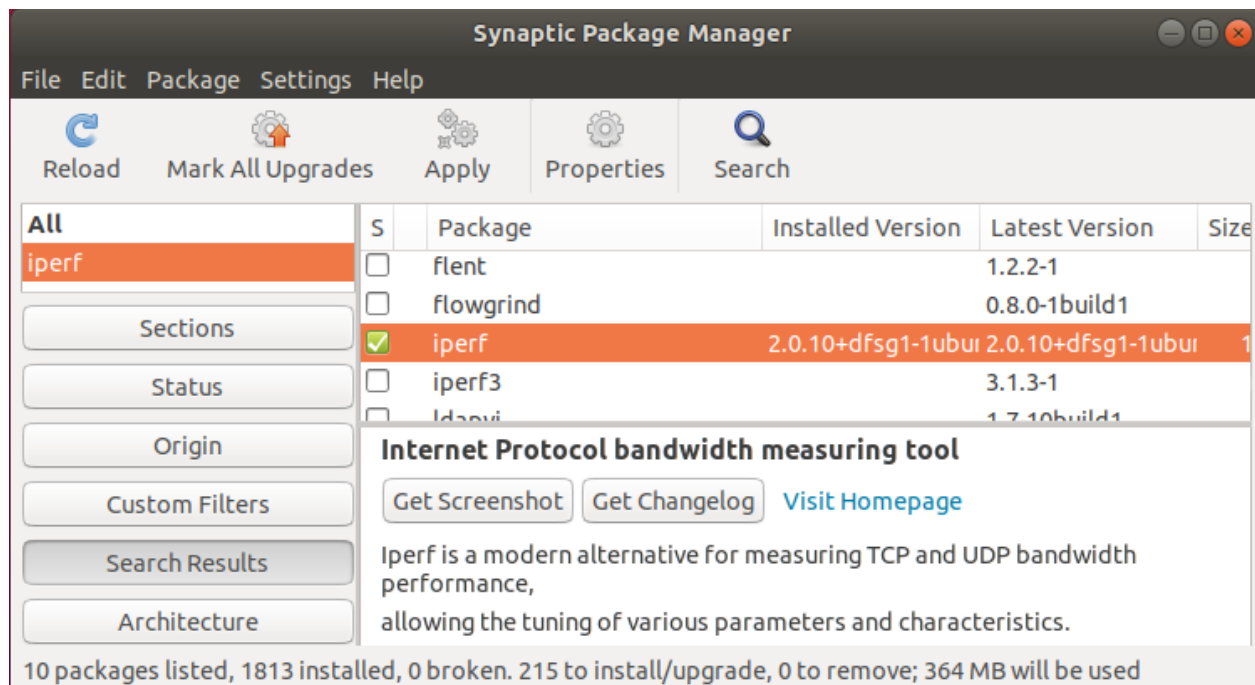

Traffic Generator:

What is iPerf?: iPerf is a tool for performing network throughput measurements. It can test either TCP or UDP throughput. To perform an iperf test the user must establish both a server (to discard traffic) and a client (to generate traffic). For each test it reports the bandwidth, loss, and other parameters

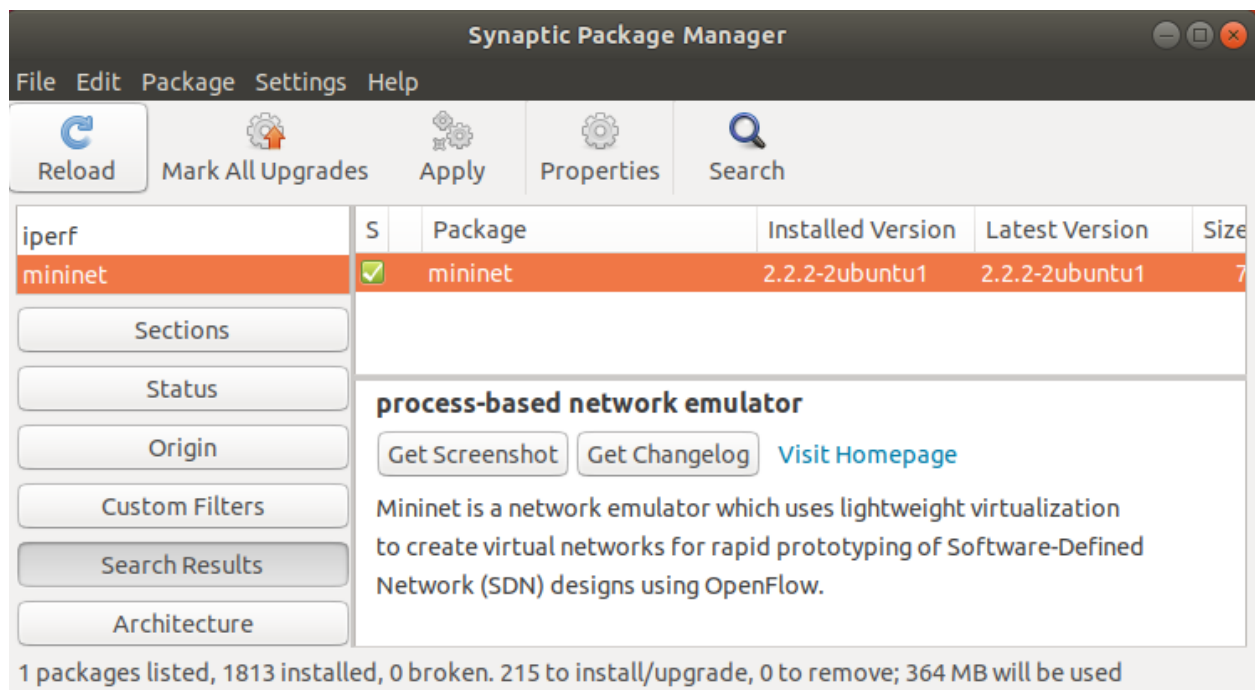

Mininet: Mininet creates a realistic virtual network, running real kernel, switch and application code, on a single machine (VM, cloud or native) Because you can easily interact with your network using the Mininet CLI (and API), customize it, share it with others, or deploy it on real hardware, Mininet is useful for development, teaching, and research. Mininet is also a great way to develop, share, and experiment with OpenFlow and Software-Defined Networking systems

Methodology:

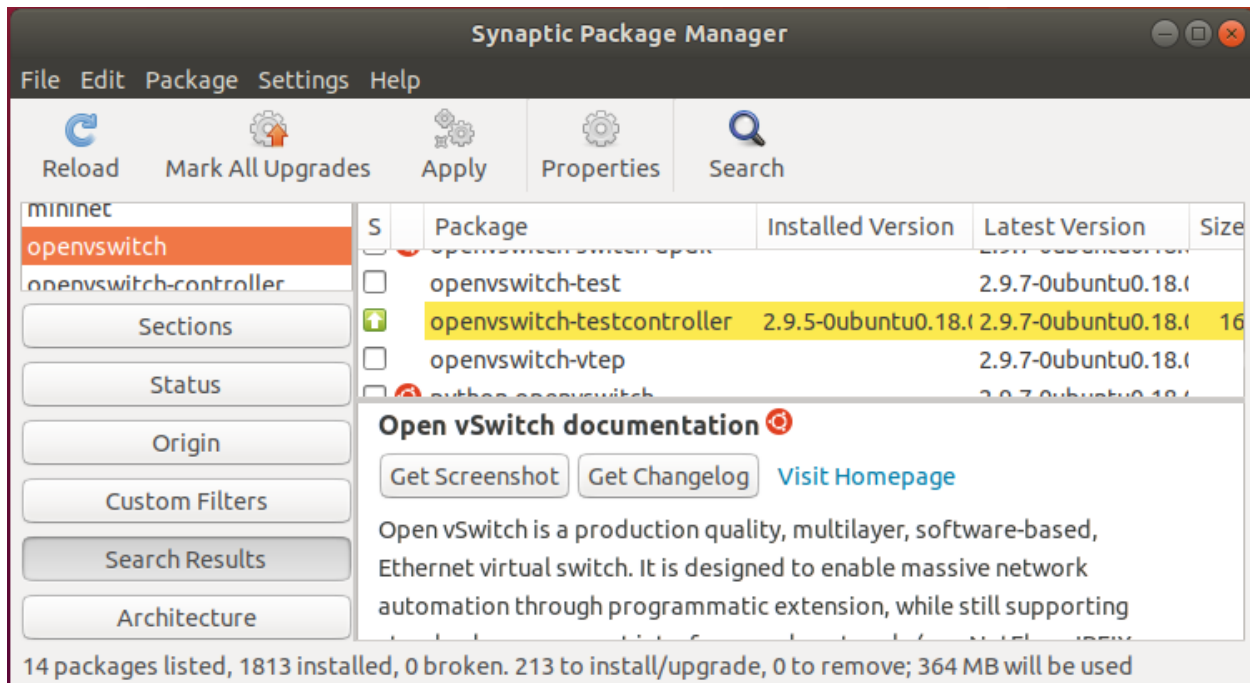

Install iperf:

Install mininet:

Install Controller:

Exercises:

Exercise 4.1.1: Open a Linux terminal, and execute the command line `iperf --help`. Provide four configuration options of `iperf`.

iperf --help

```
shakhera@shakhera-HP-Notebook-PC: ~
File Edit View Search Terminal Help
shakhera@shakhera-HP-Notebook-PC:~$ iperf --help
Usage: iperf [-s|-c host] [options]
       iperf [-h|--help] [-v|--version]

Client/Server:
  -b, --bandwidth #[kmgKMG | pps]  bandwidth to send at in bits/sec or packets p
er second
  -e, --enhancedreports             use enhanced reporting giving more tcp/udp and traffi
c information
  -f, --format [kmgKMG]            format to report: Kbits, Mbits, KBytes, MBytes
  -i, --interval #                 seconds between periodic bandwidth reports
  -l, --len #[kmKM]                length of buffer in bytes to read or write (Default
s: TCP=128K, v4 UDP=1470, v6 UDP=1450)
  -m, --print_mss                  print TCP maximum segment size (MTU - TCP/IP header)
  -o, --output <filename>         output the report or error message to this specifie
d file
  -p, --port #                     server port to listen on/connect to
  -u, --udp                        use UDP rather than TCP
      --udp-counters-64bit         use 64 bit sequence numbers with UDP
  -w, --window #[KM]              TCP window size (socket buffer size)
  -z, --realtime                   request realtime scheduler
  -B, --bind <host>               bind to <host>, an interface or multicast address
  -C, --compatibility              for use with older versions does not sent extra msgs
  -M, --mss #                     set TCP maximum segment size (MTU - 40 bytes)
```

Exercise 4.1.2: Open two Linux terminals, and configure terminal-1 as client (`iperf -c IPv4_server_address`) and terminal-2 as server (`iperf -s`). Note: use the loopback address. Which are the statistics provided at the end of transmission?

In terminal -1:

To run client in terminal, the command line is: `iperf -c 127.0.0.1`

```
shakhera@shakhera-HP-Notebook-PC: ~
File Edit View Search Terminal Help
shakhera@shakhera-HP-Notebook-PC:~$ iperf -c 127.0.0.1
-----
Client connecting to 127.0.0.1, TCP port 5001
TCP window size: 2.50 MByte (default)
-----
[ 3] local 127.0.0.1 port 60498 connected with 127.0.0.1 port 5001
[ ID] Interval      Transfer    Bandwidth
[ 3]  0.0-10.0 sec  32.6 GBytes 28.0 Gbits/sec
shakhera@shakhera-HP-Notebook-PC:~$ |
```

In terminal -2:

In server, the command line is: *iperf -s*

```
shakhera@shakhera-HP-Notebook-PC: ~
File Edit View Search Terminal Help
shakhera@shakhera-HP-Notebook-PC:~$ iperf -s
-----
Server listening on TCP port 5001
TCP window size: 128 KByte (default)
-----
[ 4] local 127.0.0.1 port 5001 connected with 127.0.0.1 port 60498
[ ID] Interval      Transfer      Bandwidth
[ 4] 0.0-10.0 sec  32.6 GBytes  28.0 Gbits/sec
```

Exercise 4.1.3: Open two Linux terminals, and configure terminal-1 as client and terminal-2 as server for exchanging UDP traffic, which are the command lines? Which are the statistics are provided at the end of transmission? What is different from the statistics provided in exercise 4.1.1.

For terminal -1:

To run client for exchanging UDP traffic, the command line is: *iperf -c 127.0.0.1 -u*

```
shakhera@shakhera-HP-Notebook-PC:~$ iperf -c 127.0.0.1 -u
-----
Client connecting to 127.0.0.1, UDP port 5001
Sending 1470 byte datagrams, IPG target: 11215.21 us (kalman adjust)
UDP buffer size: 208 KByte (default)
-----
[ 3] local 127.0.0.1 port 44878 connected with 127.0.0.1 port 5001
[ ID] Interval      Transfer      Bandwidth
[ 3] 0.0-10.0 sec  1.25 MBytes  1.05 Mbits/sec
[ 3] Sent 893 datagrams
[ 3] Server Report:
[ 3] 0.0-10.0 sec  1.25 MBytes  1.05 Mbits/sec  0.000 ms  0/ 893 (0%)
shakhera@shakhera-HP-Notebook-PC:~$ |
```

For terminal -2:

In server for exchanging UDP traffic, the command line is: *iperf -s -u*

```
shakhera@shakhera-HP-Notebook-PC:~$ iperf -s -u
-----
Server listening on UDP port 5001
Receiving 1470 byte datagrams
UDP buffer size: 208 KByte (default)
-----
[ 3] local 127.0.0.1 port 5001 connected with 127.0.0.1 port 44878
[ ID] Interval      Transfer      Bandwidth      Jitter    Lost/Total Datagrams
[ 3] 0.0-10.0 sec  1.25 MBytes  1.05 Mbits/sec  0.008 ms  0/ 893 (0%)
|
```

Exercise 4.1.4: Open two Linux terminals, and configure terminal-1 as client and terminal-2 as server for exchanging UDP traffic, with:

- Packet length = 1000bytes
- Time = 20 seconds
- Bandwidth = 1Mbps
- Port = 9900

Which are the command lines?

For terminal -1:

To run client for exchanging UDP traffic, with packet length, time, bandwidth and port, the command line is: *iperf -c 127.0.0.1 -u -l 1000 -t 20 -b 1M -p 9900*

```
shakhera@shakhera-HP-Notebook-PC:~$ iperf -c 127.0.0.1 -u -l 1000 -t 20 -b 1 -p 9900
iperf: ignoring extra argument -- 20
WARNING: delay too large, reducing from 8000.0 to 1.0 seconds.
-----
Client connecting to 127.0.0.1, UDP port 9900
Sending 1000 byte datagrams, IPG target: 8000000000.00 us (kalman adjust)
UDP buffer size: 208 KByte (default)
-----
[ 3] local 127.0.0.1 port 39778 connected with 127.0.0.1 port 9900
[ ID] Interval      Transfer    Bandwidth
[ 3] 0.0-12.0 sec  11.7 KBytes 8.00 Kbits/sec
[ 3] Sent 12 datagrams
[ 3] Server Report:
[ 3] 0.0-12.0 sec  11.7 KBytes 8.00 Kbits/sec  0.000 ms  0/ 12 (0%)
shakhera@shakhera-HP-Notebook-PC:~$
```

For terminal -2:

In server for exchanging UDP traffic, the command line is: *iperf -s -u -p 9900*

```
shakhera@shakhera-HP-Notebook-PC:~$ iperf -s -u -p 9900
-----
Server listening on UDP port 9900
Receiving 1470 byte datagrams
UDP buffer size: 208 KByte (default)
-----
[ 3] local 127.0.0.1 port 9900 connected with 127.0.0.1 port 39778
[ ID] Interval      Transfer    Bandwidth      Jitter    Lost/Total Datagrams
[ 3] 0.0-12.0 sec  11.7 KBytes 8.00 Kbits/sec  0.000 ms   0/ 12 (0%)
```

Exercise 4.2.1: Open two Linux terminals, and execute the command line `ifconfig` in terminal-1. How many interfaces are present?

In terminal-2, execute the command line `sudo mn`, which is the output?

In terminal-1 execute the command line `ifconfig`. How many real and virtual interfaces are present now?

In terminal-1:

The *ifconfig* command shows active network interfaces. This is generally the primary network interface – usually `eth0` and the loopback address as shown in the example below.

```
shakhera@shakhera-HP-Notebook-PC:~$ ifconfig
enp0s3: flags=4163<UP,BROADCAST,RUNNING,MULTICAST> mtu 1500
    inet 10.0.2.15 netmask 255.255.255.0 broadcast 10.0.2.255
    inet6 fe80::90d6:8cf8:3ad9:8238 prefixlen 64 scopeid 0x20<link>
    ether 08:00:27:25:23:01 txqueuelen 1000 (Ethernet)
    RX packets 4343 bytes 5380624 (5.3 MB)
    RX errors 0 dropped 0 overruns 0 frame 0
    TX packets 2418 bytes 204388 (204.3 KB)
    TX errors 0 dropped 0 overruns 0 carrier 0 collisions 0

lo: flags=73<UP,LOOPBACK,RUNNING> mtu 65536
    inet 127.0.0.1 netmask 255.0.0.0
    inet6 ::1 prefixlen 128 scopeid 0x10<host>
    loop txqueuelen 1000 (Local Loopback)
    RX packets 2305334 bytes 66385543417 (66.3 GB)
    RX errors 0 dropped 0 overruns 0 frame 0
    TX packets 2305334 bytes 66385543417 (66.3 GB)
    TX errors 0 dropped 0 overruns 0 carrier 0 collisions 0
```

```
shakhera@shakhera-HP-Notebook-PC:~$ |
```

In terminal-2: *Sudo mn*

```
shakhera@shakhera-HP-Notebook-PC:~$ sudo mn
[sudo] password for shakhera:
*** Creating network
*** Adding controller
*** Adding hosts:
h1 h2
*** Adding switches:
s1
*** Adding links:
(h1, s1) (h2, s1)
*** Configuring hosts
h1 h2
*** Starting controller
c0
*** Starting 1 switches
s1 ...
*** Starting CLI:
mininet>
```

In terminal-1:

The *ifconfig* command shows active network interfaces. Usually the interface of eth0, loopback address, eth1 and eth2 are as shown in the example below.

```
shakhera@shakhera-HP-Notebook-PC: ~  
File Edit View Search Terminal Help  
shakhera@shakhera-HP-Notebook-PC:~$ ifconfig  
enp0s3: flags=4163<UP,BROADCAST,RUNNING,MULTICAST> mtu 1500  
    inet 10.0.2.15 netmask 255.255.255.0 broadcast 10.0.2.255  
    inet6 fe80::90d6:8cf8:3ad9:8238 prefixlen 64 scopeid 0x20<link>  
    ether 08:00:27:25:23:01 txqueuelen 1000 (Ethernet)

    TX packets 33 bytes 3699 (3.6 KB)  
    TX errors 0 dropped 0 overruns 0 carrier 0 collisions 0
```

Exercise 4.2.2: Interacting with mininet; in terminal-2, display the following command lines and explain what it does:

- mininet> help
- mininet> nodes
- mininet> net
- mininet> dump
- mininet> h1 ifconfig -a

- mininet> s1 ifconfig -a
- mininet> h1 ping -c 5 h2
- Draw the network topology that is created in mininet:

In terminal-2:

mininet> help

```
shakhera@shakhera-HP-Notebook-PC: ~
File Edit View Search Terminal Help
mininet> help

Documented commands (type help <topic>):
=====
EOF      gterm  iperfudp  nodes      pingpair    py      switch
dpctl    help   link      noecho     pingpairfull  quit    time
dump     intfs  links     pingall    ports       sh      x
exit     iperf  net       pingallfull  px          source  xterm

You may also send a command to a node using:
  <node> command {args}
For example:
  mininet> h1 ifconfig

The interpreter automatically substitutes IP addresses
for node names when a node is the first arg, so commands
like
  mininet> h2 ping h3
should work.

Some character-oriented interactive commands require
noecho:
  mininet> noecho h2 vi foo.py
```

mininet> nodes

```
mininet> nodes
available nodes are:
c0 h1 h2 s1
mininet>
```

mininet> net

```
mininet> net
h1 h1-eth0:s1-eth1
h2 h2-eth0:s1-eth2
s1 lo: s1-eth1:h1-eth0 s1-eth2:h2-eth0
c0
mininet> |
```

mininet> dump

```
mininet> dump
<Host h1: h1-eth0:10.0.0.1 pid=6726>
<Host h2: h2-eth0:10.0.0.2 pid=6728>
<OVSSwitch s1: lo:127.0.0.1,s1-eth1:None,s1-eth2:None pid=6733>
<Controller c0: 127.0.0.1:6653 pid=6719>
mininet>
```

mininet> h1 ifconfig -a: You should see the host's h1-eth0 and loopback lo interfaces. Note that this interface h1-eth0 is not seen by primary Linux system when ifconfig is run, because it is specific to the network namespace of the host process.

```
mininet> h1 ifconfig -a
h1-eth0: flags=4163<UP,BROADCAST,RUNNING,MULTICAST> mtu 1500
    inet 10.0.0.1 netmask 255.0.0.0 broadcast 10.255.255.255
    inet6 fe80::c4aa:6dff:fe69:b978 prefixlen 64 scopeid 0x20<link>
    ether c6:aa:6d:69:b9:78 txqueuelen 1000 (Ethernet)
    RX packets 41 bytes 4370 (4.3 KB)
    RX errors 0 dropped 0 overruns 0 frame 0
    TX packets 12 bytes 936 (936.0 B)
    TX errors 0 dropped 0 overruns 0 carrier 0 collisions 0

lo: flags=73<UP,LOOPBACK,RUNNING> mtu 65536
    inet 127.0.0.1 netmask 255.0.0.0
    inet6 ::1 prefixlen 128 scopeid 0x10<host>
    loop txqueuelen 1000 (Local Loopback)
    RX packets 0 bytes 0 (0.0 B)
    RX errors 0 dropped 0 overruns 0 frame 0
    TX packets 0 bytes 0 (0.0 B)
    TX errors 0 dropped 0 overruns 0 carrier 0 collisions 0

mininet> |
```

mininet> s1 ifconfig -a: This will show the switch interfaces, plus the MV's connection out eth0. For other examples highlighting that the hosts have isolated network state, run arp and route on both s1 and h1.

```

mininet> s1 ifconfig -a
enp0s3: flags=4163<UP,BROADCAST,RUNNING,MULTICAST> mtu 1500
    inet 10.0.2.15 netmask 255.255.255.0 broadcast 10.0.2.255
    inet6 fe80::90d6:8cf8:3ad9:8238 prefixlen 64 scopeid 0x20<link>
    ether 08:00:27:25:23:01 txqueuelen 1000 (Ethernet)

s1
*** Stopping 2 hosts
h1 h2
*** Done
completed in 854.767 seconds
shakhera@shakhera-HP-Notebook-PC:~$ |
```

Exercise 4.2.3: In terminal-2, display the following command line: `sudo mn --link tc,bw=10,delay=500ms`

- `mininet> h1 ping -c 5 h2`, What happen with the link?
- `mininet> h1 iperf -s -u &`
- `mininet> h2 iperf -c IPv4_h1 -u`, Is there any packet loss?

Modify iperf for creating packet loss in the mininet network, which is the command line?

In terminal-2:

```
shakhera@shakhera-HP-Notebook-PC:~$ sudo mn --link tc,bw=10,delay=500ms
[sudo] password for shakhera:
*** Creating network
*** Adding controller
*** Adding hosts:

Question: Explain how the traffic generators work?

Answer:

Traffic generators are a way of injecting traffic into a network for utilization by other devices.

A traffic generator is meant to look like a device on a network, so it can target devices in receipt of traffic. This meant it will have a physical, typically higher-level address.

When implemented, a traffic generator attaches to the network via the same interfaces as other devices to establish brand-new packets. Certain traffic generators may also need to respond to traffic from other devices, for example, when they need to establish an Address Resolution Protocol (ARP) in an IP network or a TCP connection.

Question: Which is the main difference between configuring UDP and TCP traffic?

Answer:

TCP and UDP have many differences and similarities. They are the most commonly used protocols for sending packets over the internet. They both work on the transport layer of the TCP/IP protocol stack and both use the IP protocol.

TCP is a connection-oriented protocol. Connection-orientation means that the communicating devices should establish a connection before transmitting data and should close the connection after transmitting the data.

TCP is used by HTTP, HTTPS, FTP, SMTP and Telnet.

UDP is the Datagram oriented protocol. This is because there is no overhead for opening a connection, maintaining a connection, and terminating a connection. UDP is efficient for broadcast and multicast type of network transmission. UDP is used by DNS, DHCP, TFTP, SNMP, RIP, and VoIP.

Question: In your opinions which are the main advantages and disadvantages of working with mininet? Provide at least 3.

Answer:

Advantages:

- Provides a simple and inexpensive **network testbed** for developing OpenFlow applications
- Includes a **CLI** that is topology-aware and OpenFlow-aware, for debugging or running network-wide tests
- also Provides a straightforward and extensible **Python API** for network creation and experimentation

disadvantage:

- Mininet-based networks cannot (currently) exceed the CPU or bandwidth available on a single server.
- Mininet cannot (currently) run non-Linux-compatible OpenFlow switches or applications; this has not been a major issue in practice.

Question: What is the advantage of having a programmable Controller?

Answer:

There are some advantages of programmable Controller are given below,

- It has very faster scan time.
- It has capable to communication with computer in plant.
- It has great computational capabilities.
- It has shorter training time required.
- A wide range of control application.
- It Have interfacing for inputs and outputs already inside the controller.
- It is easily programmed and has an easily understood programming language.

- It has flexibility in programming and reprogramming.
- It has shorter project implementation time.
- It has reliability in operation

Discussion: From this lab, I have to know that how to Install and use traffic generators as powerful tools for testing network performance, and how to configure SDN Controller. To perform this lab I have to understand how the mininet simulator works, and how implement and run basic examples for understanding the role of the controller and how it interact with mininet.

In conclusion, it will suffice to say that TCP and UDP, two popular transport layer protocols, cannot be done without in any way. The selection between TCP vs UDP can be done via application developers and in line with user application connection requirements. From the above exercise we have learned the mechanism to sent some messages using UDP protocol.

Mininet is a useful tool for teaching, development and research. With it, a realistic virtual network, running a real kernel switch and application code, can be set up in a few seconds on a single machine, either virtual or native. It is actively developed and supported.
